Does broadband Internet affect fertility in Germany?

Quel lien entre Internet haut débit et fécondité en Allemagne ?

[Francesco Billari, Osea Giuntella, Luca Stella](#)

Using German data, Francesco Billari, Osea Giuntella and Luca Stella test whether broadband Internet influences fertility choices in a low-fertility setting. They find positive effects of high-speed Internet on the fertility of highly educated women aged 25-45. They then show that broadband Internet allows highly educated women to reconcile career and motherhood, which may promote a “digital divide” in fertility.

A key aspect of the digital revolution that has modified lives at the beginning of the twenty-first century is the rapid diffusion of the Internet, and access to high-speed (broadband) Internet in particular. The profound social and economic implications of the Internet’s spread have been underlined by social science scholars since its inception (DiMaggio et al. 2001). More recently, researchers have also started to focus on the effect of the Internet on family life, in terms of both daily and longer-term schedules.

In a recent study (Billari et al. 2019), we investigate whether the diffusion of high-speed Internet has an impact on fertility in a low-fertility setting, that of Germany, a country where the total fertility rate has remained stable at around 1.35 children per woman for several years now. Related empirical studies have focused on the effect of the Internet on marriage rates (Bellou 2015), labour force participation of married women (Dettling 2017), and teenage fertility (Guldi and Herbst 2017) in the United States. But little is known about the effects of Internet on general fertility, of both sexes, and outside the US.

Data

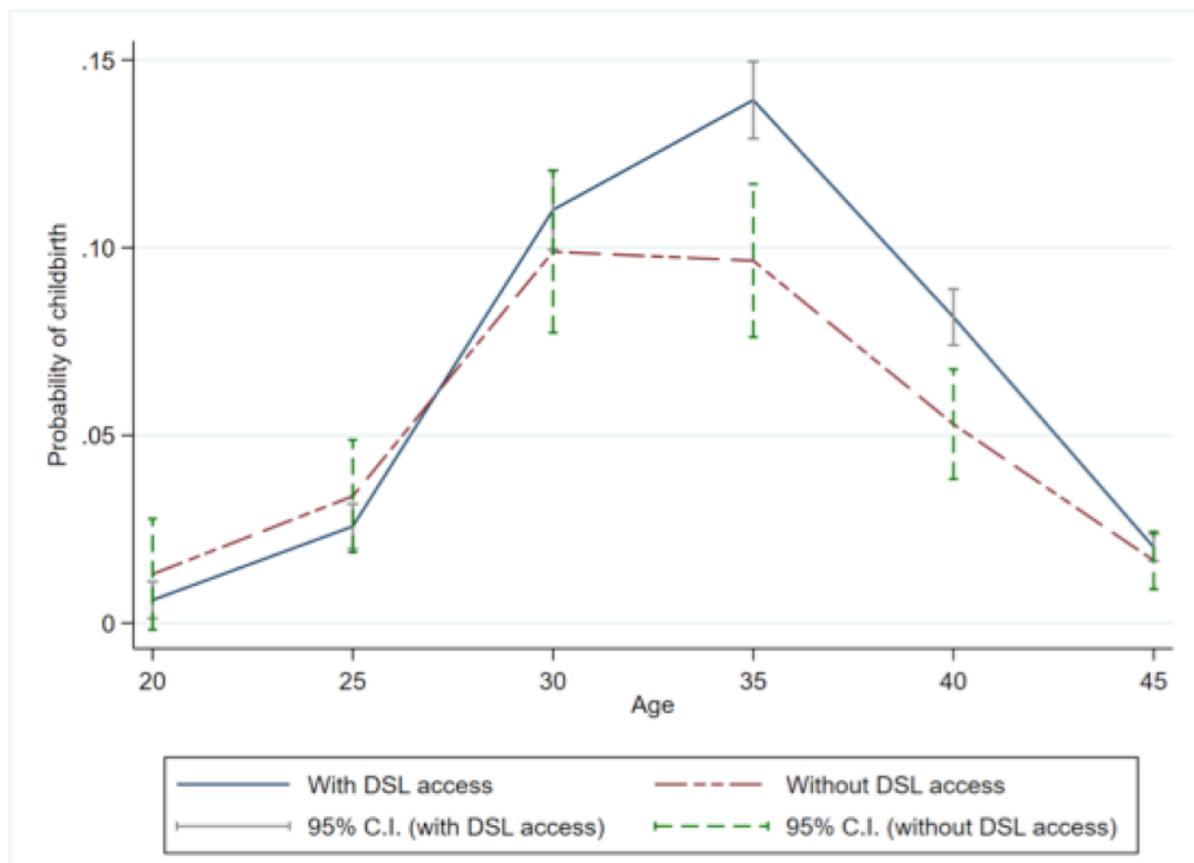

We use data from the German Socio-Economic Panel (SOEP), a longitudinal panel dataset about the German population. These data are uniquely suited to studying the effect of broadband diffusion on fertility. First, they contain retrospective life course information, including fertility histories. Second, they contain household information not only on Internet access, but also on access via broadband

technology (digital subscriber line, DSL). This information is exploited to build our key explanatory variable. Lastly, the SOEP also contains rich information on individuals' life courses and conditions, including working from home, other labour market behaviour, time spent on childcare, and life satisfaction; thereby enabling us to shed light on the potential mechanisms whereby high-speed Internet access may affect fertility.

The (causal?) association between home broadband Internet access and fertility

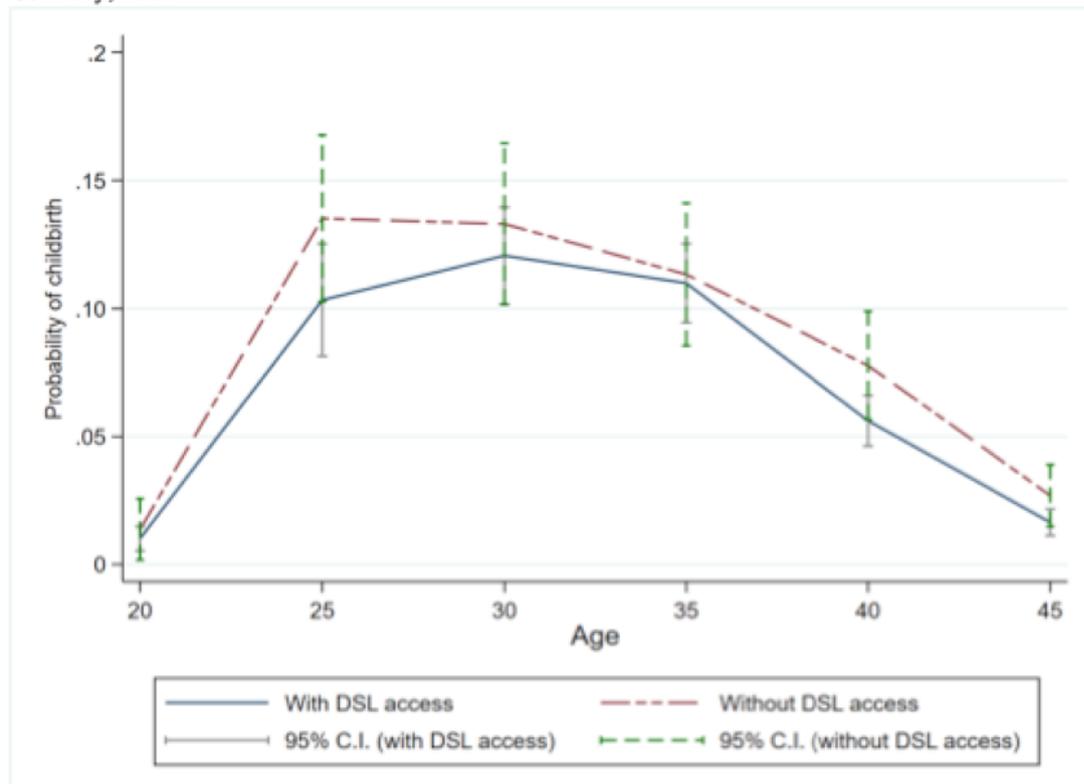

In Figures 1 and 2, we analyse age differences in fertility according to access to DSL among highly educated and less-educated individuals, respectively. Overall, the pattern that emerges is that broadband Internet access at home is positively correlated with the probability of a birth, but only among highly educated individuals older than 25. The opposite pattern is seen among less-educated individuals. However, it is not clear whether this correlation is driven by selection on unobservable factors or by a causal effect.

Figure 1 Annual probability of childbirth by DSL access and age: highly educated individuals, Germany 2008–12

Source: Authors' analysis of SOEP data.

Figure 2 Annual probability of childbirth by DSL access and age: less-educated individuals Germany, 2008–12

Source: As for Figure 1.

We exploit an instrumental variable (IV) strategy (along the lines suggested by Falck et al. 2014) to investigate whether DSL availability has causally increased fertility. Table 1 provides the results of this analysis by education group for individuals aged 25-45. We find a positive and significant effect of DSL on fertility only among highly educated women (see column 3), whose fertility is thus increased by about 13.3 percentage points. The effect is also positive among highly educated men (7%), but is not statistically significant. Finally, the coefficient is negative, and, again, not significant, among the less educated.

Discussion

What might be the factors underlying the relationship between broadband use and fertility? Taking into account the relevant literature, the Internet may affect fertility through three main mechanisms: information, marriage, and work-family balance.

To test for the relative role of information, we analyse the relationship between low-speed Internet and fertility. While working from home may require high-speed Internet, people can still obtain information with access to a low-speed Internet

connection only. Our analysis (see Table A26 of our article) suggests that information plays a limited role in explaining the positive effects of broadband on fertility.

Broadband access may also affect fertility through its potential effects on marriage (Bellou, 2015). We find a positive but non-significant relationship between access to high-speed Internet and the likelihood of marriage for highly educated women aged 25-45 (see column 1 of Table 2).

Table 1 Effects of broadband on fertility by education and sex: individuals aged 25–45, Germany 2008–12

Sex and education group:	(1)	(2)	(3)	(4)	(5)	(6)
	All Highly educated	All Less-educated	Women Highly educated	Women Less-educated	Men Highly educated	Men Less-educated
Dependent variable: birth in current year						
DSL subscription	0.108* (0.059)	-0.032 (0.112)	0.133** (0.062)	-0.074 (0.124)	0.070 (0.065)	0.034 (0.147)
Mean of dependent variable	0.075	0.070	0.072	0.063	0.079	0.076
Standard deviation of dependent variable	0.263	0.255	0.258	0.244	0.269	0.265
F-test of excluded instruments	18.52	5.049	15.52	4.948	12.08	2.826
Observations	19,818	8,689	11,710	4,323	8,108	4,366

Notes: Standard errors are reported in parentheses and are clustered at the household level. All models include controls for education, age and its quadratic term, sex, an indicator for rural area, marital status, occupational status, migration background, and log of net household income. All regressions further include state and survey year fixed effects, as well as state-specific time trends. The F-test for excluded instruments refers to the Kleibergen–Paap F-statistic. * Significant at 10 per cent; ** significant at 5 per cent; *** significant at 1 per cent.

Table 2 Potential mechanisms for effect of broadband on fertility: highly educated women aged 25–45, Germany 2008–12

Dependent variable:	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
	Got married	Work from home	Part-time work	Full-time work	Working hours	Not working	Childcare (weekday)	High life satisfaction
DSL subscription	0.052 (0.041)	0.294* (0.178)	0.350** (0.174)	-0.240 (0.167)	-13.37** (5.836)	-0.110 (0.142)	3.693* (1.928)	0.270** (0.133)
Mean of dependent variable	0.026	0.243	0.474	0.320	28.21	0.207	5.353	0.219
Standard deviation of dependent variable	0.160	0.429	0.499	0.466	14.10	0.405	5.982	0.414
F-test of excluded instruments	14.33	9.849	15.13	15.13	11.62	15.13	15.35	15.74
Observations	11,710	4,067	11,710	11,710	9,164	11,710	11,393	11,615

Notes: Standard errors are reported in parentheses and are clustered at the household level. All models include controls for education, age and its quadratic term, sex, an indicator for rural area, marital status, occupational status, migration background, and log of net household income. All regressions further include state and survey year fixed effects, as well as state-specific time trends. The F-test for excluded instruments refers to the Kleibergen–Paap F-statistic. * Significant at 10 per cent; ** significant at 5 per cent; *** significant at 1 per cent.

With regard to the third mechanism, DSL technology provides individuals with more opportunities to do at least part of their work from home, thereby relaxing

time constraints, especially among more educated women, and favouring the work-family balance (Dettling 2017). To test this hypothesis, we analyse the effects of DSL access on the likelihood of reporting any work from home, the likelihood of part-time vs. full-time work, working hours, and employment status, among highly educated women aged 25-45. In column 2 of Table 2, we find evidence that high-speed Internet increases the likelihood of working from home by 29.4 percentage points. Columns 3 and 4 suggest that access to DSL encourages part-time vs. full-time work. Consistent with this, in column 5 we find that the overall number of hours worked decreases with broadband access. While the point estimate in column 6 suggests a positive effect of broadband on female employment, there is no evidence of a significant effect. In columns 7 and 8, we also find that access to DSL significantly increases time spent on childcare and the likelihood of reporting a high level of life satisfaction.

Overall, our findings suggest that increasing access to high-speed Internet may promote fertility among highly educated women by easing the burden of balancing work and family duties. This may be particularly important in countries such as Germany, which lag behind other advanced economies in terms of their share of telecommuters (Brenke 2016). The downside of our findings is that broadband might introduce a “digital divide” in fertility, allowing highly educated individuals to reach their fertility goals, while not improving the chances of less-educated individuals, who tend to be employed in less flexible occupations.
