

The myth of the sandwich generation in Brazil

Maria Carolina Tomás, Everton Emanuel Campos de Lima, Bernardo Lanza Queiroz | July 2, 2018

Due to rapid and profound demographic changes, population age structure in Brazil has changed sharply in the past few years. Contrary to widespread belief, however, Maria Carolina Tomás, Everton Emanuel Campos de Lima and Bernardo Lanza Queiroz note that this process has not expanded the so-called sandwich generation: the number of middle-aged mothers who have to care for both their young children and the elderly parents with whom they co-reside is shrinking.

The demographics of the Brazilian sandwich generation

The increasing delay in fertility and the reduction in mortality have changed not only the population age structure (Castanheira and Kohler, 2017; França et al, 2017), but also family dynamics. Among other things, middle-aged women now face a much higher probability of having their elderly parents alive while still having to care for their young children. This so-called “sandwich generation”, with responsibilities towards both the younger and older generations, is a phenomenon that has attracted the attention of researchers and policy makers in recent years (Goldstein, Mason and Zagheni, 2011; Dukhovnov and Zagheni, 2015).

The operative definition of the sandwich generation may vary, depending on research objectives and data availability. It is usually defined as the middle-aged population, especially women, who have a dependent child (under 18 years old) and a living parent (aged over 65 who may need assistance). Both groups are generally assumed to be incapable of providing for their own needs, and therefore to compete for care and put the sandwich generation under pressure. Here, we adopt a slightly different definition, following Mason and Zagheni (2014): a woman is “sandwiched” if she has one or more children under the age of ten and one or more (old) parents who are less than five years away from the average age at death.

We discuss this phenomenon in Brazil, where both mortality and fertility have changed rapidly in the past few years. Fertility declined from 6.1 to 1.8 children per woman between 1950 and 2010 (when considerable postponement was also observed) whereas life expectancy increased from 50.8 years to 74.6. (Figure 1). In addition to this rapid demographic change, public transfers to the elderly are relatively high, but this has co-existed with a tradition of family support (Turra, Queiroz and Rios-Neto, 2011).

Different perspectives of the Brazilian sandwich generation

To get a glimpse of what has actually happened in Brazil in the past century or so we used [Socsim](#), a social simulation demographic model, originally conceived by Gilbert and Hammel and further developed by Hammel, Wachter and Peter Laslett. We tried alternative scenarios of fertility and mortality (all compatible with Brazil's history), but the differences between them turned out to be minor, so we will concentrate only on one of them, the most realistic, in our opinion (Lima, Tomás and Lanza Queiroz 2015).

Figure 2 – Average age of mother, grandmother, and grandfather at birth of average child – Brazil, 1920 -2015.

Figure 2 shows some of our results: while the average age of mothers at childbirth has not changed much over time (from 25 years at the beginning of the century to 30 years today - but with a large decline in fertility), the age at becoming a grandparent increased rapidly from 1920 to 1940, and then stayed roughly constant.

Figure 3 shows the prevalence of the sandwich generation from the perspective of the child, by year. What emerges very clearly is that the average time women spend sandwiched between elderly parents and young children has declined in Brazil over the past 60 years, contrary to common perceptions and to what seems to happen in most developed countries.

Figure 3 – Proportion of “sandwiched” mothers (i.e. with children less than 10 years of age and at least one parent within five years from average age at death) by year (Brazil, 1900-1990).

A limitation of our analysis is that we use a definition of sandwich generation which is not fully comparable to that used by most of the literature in developed countries. However, we do not think that this invalidates our substantive findings: Mason and Zagheni (2014), for instance, who use the same definition as we do, observed a decline in *sandwichness* for most countries in the world, explained by the reduction in fertility levels and the increase in longevity.
