The 21st century - the century of centenarians

XXIe siècle, siècle des centenaires

[George W Leeson](#)

The emergence of large numbers of centenarians has accompanied the ageing of our populations. The number of people aged 100 years and over in England and Wales, for example, increased from less than 200 in 1922 to 570 in 1961. By 1981 it had climbed to 2,418 and to 12,318 in 2012.

Around the world, new generations can expect to live longer than previous generations, and the rate of increase is surprisingly strong and constant (Leeson 2014; see also [wikipedia_Oldest_people](#)). Life expectancies at birth in England and Wales increased from 48 years for females and 44 years for males in 1900 to 71 years and 66 years respectively by 1965, and again to 84 years and 80 years, respectively, in 2014. Increases were more modest in the latter half of that century as they were driven by improvements in survival at older ages (Leeson 2014a; Vaupel 1998). Furthermore, there is a body of evidence indicating that lives will continue to be extended (for example Bongaarts 2006; Christensen et al. 2009; Vaupel 2010; Leeson 2011, 2014a).

The verified oldest person ever to have lived is Jeanne Calment, who died in France in 1997 aged 122 years 164 days. The last surviving Briton born in the 19th century was Grace Jones who died on November 14th 2014. Living in three centuries is nothing new. Margaret Neve lived in the 18th, 19th and 20th centuries (1792-1903) and is one of the earliest verified of such cases, and large proportions of those born towards the end of the 20th century will live into the 22nd century (Office for National Statistics 2012; Department for Work and Pensions 2011).

The coming of (many more of) the centenarians

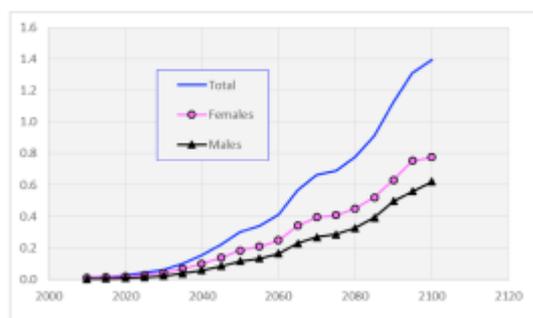

In 1922, there were just 36 male centenarians in England and Wales. This number fluctuated moderately between 24 and 48 until 1958, from when a continual increase began. From 1958 to 1970, the number of male centenarians increased from 48 to 144 by 1970, doubling to 288 by 1980. The next doubling took almost

20 years as the number reached 600 male centenarians in 1999. It then took only 9 years to 2008 to double again to 1,198 male centenarians, and by 2012, there were 1,780 male centenarians in England and Wales.

The growth in the number of female centenarians in England and Wales was similar, albeit at a higher level at every point in time after 1922. In 1922 the number of female centenarians was more than triple the number of male centenarians, namely 126, and this number fluctuated moderately between 110 and 147 for about 25 years. However, the continual increase in the number of centenarians began earlier for females than for males, in 1946 when the number increased from 142 in 1945 to 174. By 1957 this had doubled to 347, and it then doubled again to 692 in 1965. This pace of doubling continued, the number reaching 1,397 in 1974, then 2,733 in 1985 and 5,564 in 2000. By 2012 there were 10,538 female centenarians in England and Wales, six times the number of male centenarians.

What of the future?

Figure 1. Projected numbers of centenarians in England and Wales, 2010-2100 (millions).

Data provided by Office for National Statistics.

Data from the Office for National Statistics in the United Kingdom reveal that by the turn of the next century, life expectancies at birth might be 93 years for males and 95.6 years for females in England and Wales. This will lead to increasing numbers of people at extreme ages, including centenarians, as is reflected in the official forecasts of the Office for National

Statistics. Figure 1 illustrates the projected numbers of centenarians in England and Wales across the remainder of the 21st century.

As can be seen, the number of centenarians is projected to increase steadily until the end of the 21st century. In the 2010s, there are 5 times as many female as male centenarians, but by 2100 numbers of male and female centenarians are expected to reach around 620,000 and 776,000, respectively.

What if age-specific later-life mortality declines more than projected in the official forecasts of the number of centenarians? An example is presented in Leeson

(2016). Consider a scenario in which projected mortality for those aged 55 years and over decreases by an additional 5% every 5 years in relation to the official projected mortality. The number of centenarians in England and Wales by 2100 would reach around 1.8 million (Table 1). The more optimistic scenario could be fuelled, for example, by potential additional decreases brought about by medical advances such as stem cell therapies enabling 80-year olds to live to 200 years of age (Lavasani 2012).

Table 1. Numbers (thousands) of centenarians in England and Wales by sex, 2010-2100, selected years, official projections and decreasing scenario.

	2010	2020	2030	2040	2050	2060	2070	2080	2090	2100
Males:										
<i>Projected</i>	2	7	21	57	115	163	268	326	496	620
<i>Decreasing</i>	2	9	28	74	147	216	327	392	584	918
Females:										
<i>Projected</i>	10	18	41	98	183	248	394	451	632	776
<i>Decreasing</i>	10	24	56	124	227	310	469	534	734	879
Total:										
<i>Projected</i>	12	25	62	155	298	411	662	778	1128	1396
<i>Decreasing</i>	12	33	84	198	374	526	796	926	1318	1797

Note: the decreasing scenario assumes an additional 5% decrease in mortality every 5 years among those aged 55 years and over compared with the official projection.

Are individuals, families, communities and society at large prepared for this development? European populations were surprised by the fundamental changes brought about by the ageing of their populations in the latter part of the 20th century – a combination of resistance to the idea that life expectancies could exceed expectations and that mid- and late-life mortality could decline significantly. The result was that old age was pushed back to age 80 and over.

The future may also present surprises and challenges if we ignore the significantly increasing number of extreme aged individuals in our societies, with centenarians comprising increasing numbers and proportions of populations, and with old age being pushed back even further.

Challenges

The century of centenarians will be challenging in both the developed and the emerging economies of the world. The trend has fundamental consequences for the way in which individuals view and live these extending lives, but also for the way in which societal infrastructures (education, workplace, housing, transport, health and social care) will need to be adapted to the needs of these extreme-aged populations.

How could/should people begin to prepare themselves for such long lives? The future looks to presents a challenge to life course planning. It is also a challenge to current concepts of old age and retirement (is retirement even at age 75 years sustainable?). Family dynamics will be challenged by the survival of these extreme-aged generations; intergenerational succession and inheritance will be delayed, and individuals will rely on smaller families for support in frail and

dependent old age.
